Abstract

The objective of this study is to prepare and study chemical compounds for cleaning denture from locally available materials. The chemical compounds solutions were (sodium bicarbonate with alum), (sodium bicarbonate with citric acid), (sodium bicarbonate with apple vinegar), (sodium bicarbonate with clear commercial vinegar), (sodium bicarbonate with thyme oil), (saturated salt solution), (clear commercial vinegar), (alum). The main study, the effects of the chemical compounds solutions were evaluated on the (color, water Sorption and transverse strength) of heat cured denture base material. The t-test showed that the highest increase in optical density for the specimens immersed in (alum), (sodium bicarbonate +alum), (sodium bicarbonate + apple vinegar) solutions at 1/2 hr immersion and it increased more at 8 hrs immersion. The conclusions of this study showed that the safest prepared solutions on the denture base material that could be used as denture cleansers are (sodium bicarbonate{7g}with clear commercial vinegar{5ml}), (sodium bicarbonate {2g} with thyme oil {3.57g}), (saturated salt solution {40g}) at 1/2 hr and 8 hrs of immersion. While, (sodium bicarbonate {2g} with citric acid {4.57g}) solution appeared its safety at 1/2 hr immersion only.

Keywords: Alum; Citric Acid; Denture Cleaner; Saturated Salt; Sodium Carbonate; Vinegar

1. Introduction

Acrylic resin is the most employed material in the construction of removable complete and partial denture. This material began to be used since 1930. It is characterized by being strong, having a satisfactory optical property copying the oral tissue appearance, showing low water sorption and solubility and having a good dimensional stability (Anusavice, 1996; Cunningham, 2000). Denture base materials and denture teeth collect the deposits in the same manner as natural teeth (Budtz – Jorgensen et al., 2000; Yeung et al., 2000; Craig et al., 2004). Every surface in the oral cavity, natural synthetic becomes covered within about 30 minute with 0.5–1.5 μ thick precipitate of salivary glycoprotein and immunoglobulin that is termed "pellicle" (Skjorland et al., 1995; Shay, 2002). The pellicle in turn provides a substrate to which oral debris (mucin, food particles and desquamated epithelial cells and micro-organisms "bacteria and fungi" readily adhere (Carlen et al., 1998). So the denture cleanliness is an essential component of oral health to prevent malodor, poor esthetic and accumulation of plaque and Calculus with its deleterious effect on oral mucosal tissue (Dills et al., 1988). Another uneasy cosmetic concern is the stain, which accumulates on the denture surfaces as a result of various habits, namely consumption of colored foodstuff, smoking and drinking beverages (Altman et al., 1979). As such, emphasis must be on the prevention of plaque accumulation with effective plaque removal (Nikawa et al., 1998).

Chemical cleansing approach is recommended for plaque control (Pipko and EL – Sadeek, 1972; Dills et al., 1988; McCabe et al., 1995; Nikawa et al., 1995; Haselden et al., 1998) as an alternative to the mechanical approach in patients with lack of motor coordination (Odman, 1992). Numerous authors have reported the poor

hygiene of the complete dentures wearers (Jeganthan et al., 1997, Taqa et.al 2014) because the majority of denture wearers do not receive proper oral hygiene orientation from their dentists. Also the advanced age of the patient leads to a decrease in manual abilities. Knowledge of constituents of denture cleansers, their efficiency, adverse effects and safety are important needs for dental staff so they are able to instruct their patients appropriately (council on dental material and equipment Denture cleanser) (ADA, 1975).

The present study aims to: First; prepare a new formula of compound that can be used as denture cleanser. Second; evaluate the prepared compounds as denture cleansers according to ideal properties of denture cleanser (nontoxic, efficient in tea stain removal, having no adverse effect on the color, water sorption, flexural strength properties of the acrylic resin denture base material at 1/2 and 8 hrs immersion time. Third; compare a new formula with currently used commercial denture cleanser tablets (Unichem, Protefix).

2. Materials and methods

The Materials used in this study are Major – Base (type; Heat-curing resin powder and liquid Pink color, Major Prodotti dentari S.P.A Italy), Elite model gypsum (type, 3 model dental stone Zhermack SPA Rovigo, Italy), T.P. Regular (type Modelling wax (Major Prodotti dentari S.P.A, Italy), Isol Major (type Universal separating film, Major Prodotti-Dentari S.R.I Italy). The experimental design of main study: Five hundred twenty eight specimens were prepared from "Major" heat-cured acrylic resin denture base material. The specimens were divided into six groups, each test has two groups as shown in (figure 1).

2.1. Preparation of the specimens

Color and transverse strength specimens Preparation: Wax Specimen Preparation: The specimens were prepared by placing a sheet of wax against a glass slab of 2.5mm thickness for transverse strength test and sheet of wax of 1.5mm thickness for color property test. The sheets were cut by using a sharp wax knife to the desired length and width for transverse test according to ADA specifications No. 12. While for color test to fit the cuvite of

spectrophotometer in order to obtain an excellent data. The surface of wax was smoothed by piece of tissue nylon type (Hatim and kazanji, 1999). The surface against glass slab was considered the polished surface. The other surface was considered the tissue surface. Flasking, packing, curing, and deflasking was done according to the methods described in the previous studies. (Crispin and Caputo, 1979; Keyf and Etikan, 2004, Anusavice, 1996), then the specimens were stored in distilled water at specified time before each test.

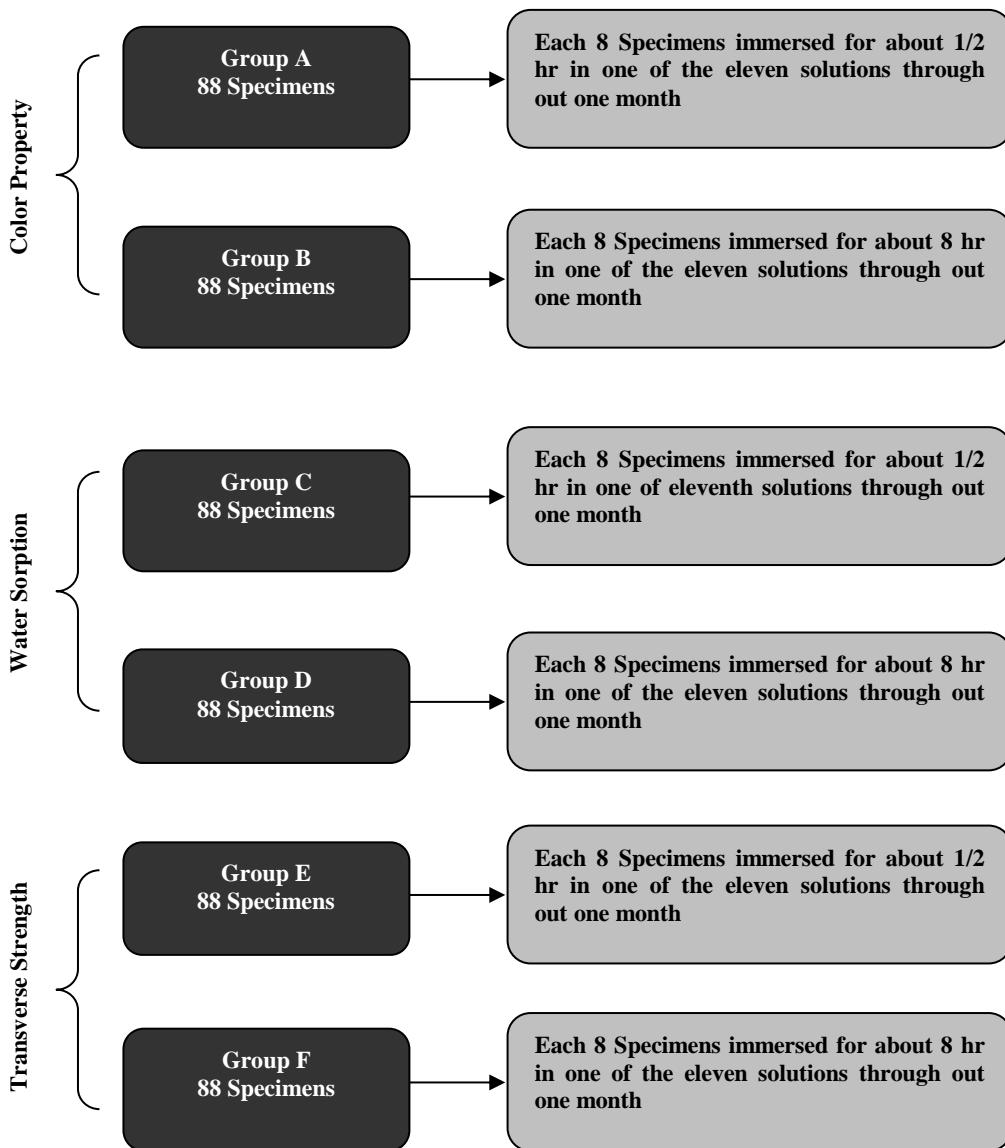

Fig. 1: Denture Base Specimens.

Note: The fresh solutions were prepared daily at the end of soaking trial (1/2 hr and 8 hrs). The solutions were removed, the beakers were cleaned and the specimens were immersed in distilled water till the next day, and so on, until it simulates the immersion of 30 days.

2.2. Preparation of tea solution

The staining agent (Tea) solution was used in this study to produce artificial staining (*In vitro*) of specimens because it is a commonly daily consumed beverage. Also it has a strong potential to stain restorative and prosthetic dental materials. Thus it has been used in many studies (Abu – Bakr et al., 2000; Lai et al., 2003; Lee et al., 2005). Eight grams of dry tea were placed in 800 ml of boiling distilled water for about four minutes and then the tea solution was filtered and allowed to cool to the room tempera-

ture. The fresh tea solution was prepared for each treatment (Jagger et al., 2002, Sheen et al., 2002).

2.3. Procedure of staining

The optical density was measured for all the specimens before staining with the tea solution "pre-staining measure" by using of Ultraviolet –Visible Spectrophotometer (CECIL). Then the specimens were immersed in the fresh human salvia and then stored in an incubator at 37°C for half hour. This will allow the formation of initial pellicle that facilitates the uptake of tea stain (Sheen et al., 2002). Then the specimens were immersed in tea solution and stored in the incubator at 37°C for one hour. Then they were removed, washed with distilled water, allowed to air drying. Then the optical density was measured for each specimen. This process has to be repeated until we gain optical density near to (2nm)

which is considered as the baseline of staining "baseline measure". This process is called stain build up technique (Jagger et al., 2002; Sheen et al., 2002).

2.4. Water sorption specimens preparation

A stainless steel die was molded in the lower half of the flask (figure 2). The stainless steel die dimensions were (50 ± 1 mm in diameter and 0.5 ± 0.05 mm in thickness). The same procedure was done for packing and curing the major denture base polymer (Crispin and Caputo, 1979; Keyf and Etikan, 2004, Anusavice, 1996). After deflasking the acrylic resin specimens were removed from their stone moulds. Any flashes of excess resin material were removed, then the specimens were numbered and a small hole was prepared in the midline of the upper part for each specimen to allow dispersion by a nylon dental floss in the solutions without contacting each other so that the specimen is surrounded by the solution only (Crispin and Caputo, 1979; Keyf and Etikan, 2004). Then the specimens (figure 3) were stored in distilled water at specified time before each test.

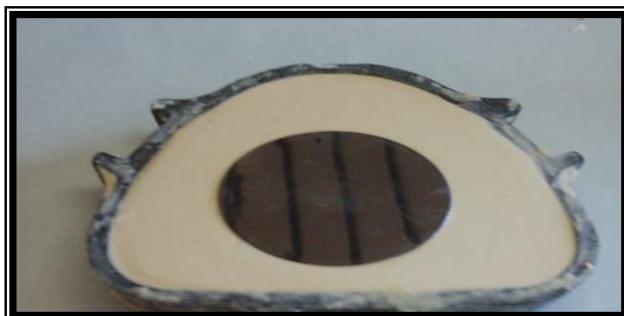

Fig. 2: Water Sorption Die.

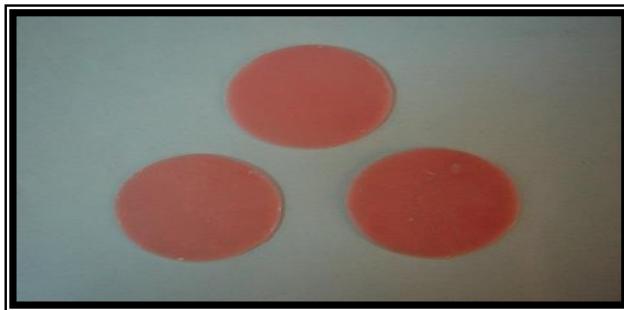

Fig. 3: Water Sorption Specimens.

2.5. Tests used in this study

The following tests are used to examine the effect of prepared and commercial tablets solutions on three properties of denture base material (color, water sorption and transverse strength).

2.5.1. Color property test

Test Specimen: Specimens were prepared as described above with dimension of ($45 \times 10 \times 1.5 \pm 0.03$ mm) (length, width, and thickness) respectively, in order to fit the cuvette of the spectrophotometer. The acrylic resin specimens were stored in the distilled water for 7 days at $37^\circ\text{C} \pm 1^\circ\text{C}$ for conditioning before testing. (Anusavice, 1996).

2.5.2. Equipment and procedure

The assessment of color property was done by using ultra violet - visible spectrophotometer (CECIL, 2000). The photometric device was used to measure the light transmitted or absorbed with specific material. The absorbed light was measured with accuracy up to 0.001 (Taqa, 2004). The maximum absorption rate for major type heat cured acrylic resin at the wave length (345nm), at which the absorbance for each specimens were measured. The specimen was

placed in the cuvette. In such a manner, the radiation source could pass through the middle area of the specimen, and then the absorbed light was measured for each specimen. The transmitted light could be calculated from the following equation: $A = 2 - \log T$ (Parikh, 1974) [A=absorbance, T=Transmittance]. The optical density for each specimen of the two groups (A, B) was measured before immersion in the solutions. Then the optical density was measured again at the end of one month of immersion in the prepared and tablets solutions to observe the change in color.

2.6. Water sorption test

Equipment and Procedure: According to the ADA specification No. 12 the specimens were dried in a desiccator containing freshly dried silica gel at $37^\circ\text{C} \pm 2^\circ\text{C}$ for 24hrs, then removed to similar desiccator at room temperature for one hour and then weighed on a digital balance. This cycle was repeated until constant weight was attained. The weight loss for each specimen was not more than 0.5 mg in 24 hrs period. This weight was considered as "Conditioned weight ". Then the specimens were immersed in the prepared and tablets solutions according to the study plan. At the end of one month of immersion, They were then removed from the solutions with tweezers, wiped with clean dry hand towel until its became free from visible moisture, waved in air for about 15 seconds and weighed on a digital balance (Sartorius, ISO 9001) with a precision of 0.0001gm. The values for water sorption were calculated for each specimen as equation of water sorption (Craig, 1989).

2.7. Transverse strength test

Test Specimen: Specimens with dimension of $65 \times 10 \times 2.5 \pm 0.3$ mm (length, width and thickness) respectively, according to ADA specification No.12. The acrylic resin specimens were stored in the distilled water for 7 days at $37^\circ\text{C} \pm 1^\circ\text{C}$ for conditioning before testing. (Anusavice, 1996).

2.7.1. Equipment and procedure

The test was done in air by using 3 points bending on an Instron testing machine. The device was supplied with a central loading plunger and two supports with polished cylindrical surfaces of 3.2 mm in diameter and 50 mm between the supports. The supports should be parallel to each other and perpendicular to the central line. The test was carried out with cross head speed of 5mm/min. The test specimen was held at each end of the two supports and the loading plunger was placed midway between he supports. The specimens were deflected until fracture occurred. The transverse strength was calculated using the equation described in previous studies. (Craig and Ward, 1997). One way analysis of variance was used to assess the significant difference between the groups at $P \leq 0.05$

3. Results

3.1. Assessment of the color change of acrylic resin denture base

3.1.1. Immersion time (1/2 hr)

The results of the t- test showed in table (1) indicate that there is no significant difference in the optical density of the acrylic resin specimens before and after immersion in the following solutions (4, 5, 6, 7, and 9), while the acrylic resin specimens that immersed in the following solutions (1, 2, 3, 8, 10, 11) show significant differences in their optical densities before and after the immersion.

Table 1: T – Test of the Optical Density for the Specimens before and After (1/2 Hr) Immersion

	Solutions	Difference of means	T – value	P – value	N
1	Soda + Alum	+ 0.040	3.930	0.006*	8
2	Soda + citric Acid	- 0.040	2.779	0.027*	8
3	Soda + apple vinegar	+ 0.030	4.583	0.003*	8
4	Soda + clear vinegar	- 0.030	2.016	0.084	8
5	Soda + thymol oil	- 0.006	0.365	0.726	8
6	Saturated salt	- 0.020	1.578	0.159	8
7	Clear vinegar	- 0.030	1.655	0.142	8

10	Unichem	- 0.060	15.875	0.000*	8
11	Protefix	- 0.042	3.930	0.006*	8

Df = 7, * Significant difference at P ≤ 0.05, - Decrease in optical density, + Increase in optical density.

3.1.2. Immersion time (8 hrs)

Table (2) reveal that there is a significant difference in the optical density of the acrylic resin specimens after immersion in all solutions of the study. Also they showed the effect of the prepared solutions on the color at 1/2 and 8 hrs immersion.

Table 2: T – Test of the Optical Density for the Specimens before and after (8 Hrs) Immersion

	Solutions	Difference of means	T-value	P – value	N
1	Soda + Alum	+ 0.100	9.504	0.000*	8
2	Soda + citric Acid	- 0.060	11.225	0.000*	8
3	Soda+apple vinegar	+ 0.060	12.000	0.000*	8
4	Soda+ clear vinegar	- 0.060	7.483	0.000*	8

10	Unichem	- 0.170	25.968	0.000*	8
11	Protefix	- 0.080	10.267	0.000*	8

Df = 7, * Significant difference at P≤ 0.05. - Decrease in optical density, + Increase in optical density.

3.2. Assessment of water sorption of acrylic resin denture base

3.2.1. Immersion time (1/2 hr)

The means and standard deviations of the water sorption in (mg/cm²) for the acrylic resin specimens immersed in different tested solutions are shown in Table (3). They showed that the highest water sorption was (0.7400 mg/cm²) for the acrylic resin specimens immersed in (Alum) solution. While the specimens immersed in (Distal water) showed the lowest water sorption (0.60 mg/cm²).

3.2.2. Immersion Time (8 hrs)

The means and standard deviations of the water sorption in (mg/cm²) for the acrylic resin specimens immersed in different tested solutions are shown in Table (4). They revealed that the highest value of water sorption was (0.80 mg/cm²) for the acrylic resin specimens immersed in (Alum) solution, while the lowest value was (0.60 mg/cm²) for the specimens immersed in (Distal water).

Table 3: Means and Standard Deviations of the Water Sorption (Mg/Cm²) for the Specimens Immersed (1/2 Hr) in Different Tested Solutions

	Solutions	Mean	S.D	N
1	Soda+ Alum	0.71	0.02563	8
2	Soda + citric Acid	0.69	0.03162	8
3	Soda + apple vinegar	0.66	0.02000	8
4	Soda + clear vinegar	0.64	0.02878	8
5	Soda + Thymol oil	0.65	0.02619	8
6	Saturated salt	0.61	0.02000	8
7	Clear vinegar	0.73	0.02878	8
8	Alum	0.74	0.02268	8
9	Distal Water	0.60	0.02000	8
10	Unichem	0.67	0.02878	8
11	Protefix	0.63	0.02726	8

Table 4: Means and Standard Deviations of the Water Sorption for the Specimens Immersed (8 Hrs) in Different Tested Solutions

	Solutions	Mean	SD	N
1	Soda+ Alum	0.73	0.02878	8
2	Soda + citric Acid	0.71	0.02000	8
3	Soda + apple vinegar	0.68	0.03586	8
4	Soda + clear vinegar	0.65	0.02879	8
5	Soda + Thymol oil	0.67	0.02001	8
6	Saturated salt	0.62	0.02887	8
7	Clear vinegar	0.76	0.02726	8
8	Alum	0.80	0.02449	8
9	Distal Water	0.60	0.02978	8
10	Unichem	0.69	0.02888	8
11	Protefix	0.64	0.02010	8

3.3. Assessment of transverse strength of acrylic resin denture base

3.3.1. Immersion time (1/2 hr)

The means and standard deviations of the transverse strength in (MPa) for the acrylic resin specimens immersed in different tested solutions are shown in Table (5).

Table 5: Means and Standard Deviations of the Transverse Strength (Mpa) for the Specimens Immersed (1/2 Hr) in Different Tested Solutions

	Solutions	Mean	SD	N
1	Soda+ Alum	79.76	2.05	8
2	Soda + citric Acid	79.94	1.58	8
3	Soda + apple vinegar	80.66	1.75	8
4	Soda + clear vinegar	81.15	1.18	8
5	Soda + Thymol oil	81	1.68	8
6	Saturated salt	81.68	1.22	8
7	Clear vinegar	79.58	2.22	8
8	Alum	79.08	1.57	8
9	Distal Water	81.86	2.48	8
10	Unichem	80.06	1.60	8
11	Protefix	81.57	1.65	8

The One Way Analysis of variance (Table 5) show that there is a significant difference ($F = 2.274$ at $P \leq 0.05$) in the transverse strength of the acrylic resin specimens immersed in the different tested solutions. The results indicates that the lowest value of transverse strength for the specimens was produced by the (Alum) solution about (79.08 MPa), while the highest value was produced by the (Distal water) which was about (81.86 MPa).

3.3.2. Immersion time (8 hrs)

The One Way Analysis of variance (Table 6) demonstrates that there is a highly significant difference ($F = 3.953$ at $P \leq 0.05$) in the transverse strength of the acrylic resin specimens immersed in the different tested solutions.

Table 6: Means and Standard Deviations of the Transverse Strength (Mpa) for the Specimens Immersed (8 Hrs) in Different Tested Solutions

Solutions	Mean	SD	N
1 Soda+ Alum	78.85	1.89	8
2 Soda + citric Acid	79.35	2.16	8
3 Soda + apple vinegar	79.96	1.84	8
4 Soda + clear vinegar	80.65	1.63	8
5 Soda + Thymol oil	80.20	1.50	8
6 Saturated salt	81.02	1.98	8
7 Clear vinegar	78.50	1.64	8
8 Alum	77.30	1.77	8
9 Distal Water	82.00	2.50	8
10 Unichem	79.71	1.87	8
11 Protefix	80.90	1.63	8

The results indicate that the lowest value of transverse strength for the acrylic resin specimens was produced by the (Alum) solution about (77.3 MPa), while the highest value was produced by the (Distal water) which was about (82 MPa).

4. Discussion

4.1. Assessment of the optical density of the denture base material

4.1.1. Immersion time (1/2 hr)

Solution No. (1) (Soda + Alum) produced a significant increase in the optical density of the specimens due to the acidic pH of the solution that leads to an increase of the water sorption value (0.71 mg/cm^2) which in turn leads to the deposition or penetration of the colorants constituents of the solution into the acrylic resin specimen (Ortengren et al., 2001). It may also be due to the gelatinous aluminum hydroxide precipitate (AL(OH)_3) that is formed when add any base to the aqueous solution of aluminum salt. When this precipitate remains for a period of time, it will change to insoluble formula which has a strength of absorbability to the colorants constituents of the solution (Holliday and Chambers, 1980).

Solution No. (2) (Soda + Citric acid) produced a significant decrease in the optical density of the acrylic resin specimens and this decrease is due to the chelation property of the sodium citrate that is produced from the reaction between the citric acid and sodium bicarbonate. This can be illustrated as sodium citrate solution has pH value close to the neutral which makes it more effective in chelation (removal of the organic and inorganic components of the deposit). Also the neutral pH is more compatible than the acidic pH (Lenarda et al., 2000). The chelation process will involve removal of colorant substances (pigments) like iron oxide (FeO) of acrylic resin material.

Solution No. (3) (Soda + Apple vinegar) produced a significant increase in the optical density of the acrylic resin specimens. This change in color is due to the staining effect of the pigment of the extracted natural apple vinegar solution and this result agrees with the (Hersek et al., 1999) who state that the PMMA was a hydrophilic material that attracted more water soluble dyes on the surface as a result of the electrostatic charges. Solution No.(4) (soda + clear vinegar), (5) (soda + thymol oil), (6) (saturated salt solution) produced non-significant difference in the optical density of the acrylic resin specimen. Also solution No. (7) (Clear vinegar), the clear vinegar solution has insignificant effect on the color and this result agrees with (Asmussan, 1983) who found that the low pH of the storage solution had little effect on the color of the acrylic resin material. Solution No. (8) (Alum) produced a significant increase in the optical density of the acrylic resin specimen. This may be due to the fact that when the no aqueous solution of the aluminum salt dissolved in the water the eighth surfaces aluminum ion formed $[\text{Al}(\text{H}_2\text{O})_6]^{+3}$ (equation no 1). It will then hydrolyze to form $(\text{H}_3\text{O})^+$ that gives acidity to the solution:

The high acidity of the solution leads to an increase in water sorption and this in turn leads to precipitation of the colorants constituent of the alum solution. Solutions No. (10, 11) (Unichem, Protefix tablets) produced a significant decrease in the optical density of the acrylic resin specimen and this may be related to the following causes: first: The chelation property of the sodium citrate that results from the reaction between the citric acid and sodium bicarbonate. Second: Sodium per borate $\text{NaBO}_2\text{H}_2\text{O}_2\cdot 3\text{H}_2\text{O}$ that contains the bleaching agent (H_2O_2) which dissociates when it comes in contact with water to release a free radical of (O_2) which has a strong oxidizing property and is considered as an active factor in cleaning process. This result agrees with (Ma et al., 1997) who reported that heat cured acrylic resin specimens became lighter in color after 7 days of immersion in hydrogen peroxide solution. Third: The decrease in optical density may be due to the effect of the detergent component of the tablet (sodium lauryl sulfate).

4.1.2. Immersion time (8 hrs)

The effect of the solutions on the optical density of the acrylic resin specimen has the same sequence as at 1/2 hr immersion time but it was large in magnitude, except for the solution no. (4) (Soda + Clear vinegar) that produced a significant decrease in optical density. This may be due to the chelation activity of the sodium acetate that is formed from the reaction of clear vinegar with sodium bicarbonate. Sodium acetate has one carboxyl group that make its chelation activity less than that of sodium citrate which has three carboxyl groups.

4.2. Assessment of the water sorption of denture base material

4.2.1. Immersion time (1/2 hr)

The water sorption values for the specimens immersed in the following solutions (2, 3, 4, 5, 6, 10, and 11) were within the ADA specification limit. Solution No. (1) (Soda + alum): The water sorption value was (0.71 mg/cm^2). This value was slightly above the ADA specification limit and this may be due to the following causes: first: The acidic pH of the solution leads to an increase in the diffusion rate of the water into the acrylic resin specimen (Ortengren et al., 2001).second: The formation of the gelatinous aluminum hydroxide that has high absorbability rate (Holliday and Chambers 1980). Solution No. (7) (Clear vinegar): Vinegar is considered as acidic solvent. This property of the solution leads to the softening of the surface layer of acrylic resin material and decreases inter chain forces and this will allow the water molecules to penetrate the material. Solution No. (8) (Alum) has a low pH value (3.2), so it behaves as a strong acid solution that increases the water sorption out of the ADA specification limit. This result agrees with (Ortengren et al., 2001) who found that water sorption for three types of composite resins increases at pH 4, 6 with increase in storage time.

4.2.2. Immersion time (8 hrs)

Water sorption value for the specimens immersed in the following solutions (3, 4, 5, 6, 10, 11) is still within the ADA specification limit, while the water sorption value for the specimen immersed in the following solutions (1, 7, 8) is out of the ADA specification limit. The specimens immersed in the solution No (2) (Soda + Citric acid) showed water sorption value out of the ADA specification limit. This may be due to the increase in storage time, which means that the longer exposure of the acrylic resin surfaces to the strong chelating activity of the sodium citrate may lead to roughened acrylic surface which in turn increases and accelerates the water sorption process. This result agrees with (Rahal et al., 2005) who found that the rough surfaces of acrylic resin material increase water sorption and accelerate the rate of water molecule penetration.

4.3. Assessment of the transverse strength of the denture base material

4.3.1. Immersion time (1/2 hr)

All the tested solutions produced an effect on the transverse strength of the specimens close to the effect of the distal water with slight difference. The lowest values of the transverse strength of acrylic resin specimen produced by the following solutions (Alum + Soda), (Clear vinegar), (Alum) may be due to the acidity of the solutions and its damaging effect on the denture base material. The high acidity of the solution leads to an increase in water sorption and this in turn leads to an increase the plasticizing effect of the penetrated water molecules. Al – Dabagi (2001) found that 5% of the vinegar solution decreased the transverse strength of the heat cured acrylic specimen through out one week of immersion. He also found that the vinegar increased the surface roughness of the specimens. Pavarina et al., (2003) found that the 90 days of water immersion period decreased the hardness and transverse strength of the acrylic resin due to the plasticizing action of the water molecules that entered between the chains of the polymer.

4.3.2. Immersion time (8 hrs)

The effect of the tested solutions on the transverse strength of acrylic resin specimen still had the same sequence with increase in the magnitude due to the increase of the storage time. The (Alum) solution still has the lowest value, followed by (clear vinegar) solution then followed by (Alum + Soda). Note: The transverse strengths of the acrylic resin specimens immersed in all tested solutions for 1/2 and 8 hrs were still within the ADA specification limit (60 – 80 MPa).
