### Abstract

The curricula scheduling is very significant and largely studied problem in academia. The desired solution calculatedly assembles the academic events over the carefully designed layout considering several predefined interlinked constraints. The contemporary research for solving scheduling constraints is inclined to raise the degree of generality, so that a wide range of identical problems may be addressed. The hyper-heuristic is such a state-of-the-art solving technique which stands on multi-layered framework. The top layer usually consists of classic algorithm for managing the operators on down-layers, and the same is occasionally assisted by machine learning or similar techniques. This research article examines the performance of the small group of bespoke low level heuristics. These LLHs are operated by hyper-heuristic to address the specific scheduling constraints. The set of heuristics are divided into a range of subgroups including timescale category which contain two subsets Day and Period. The utility group which contains two patterns named Shift and Swap techniques, while the third category encircles three more subgroups of Random or Sami-Random and Progressive.

**Keywords:** Curricula Scheduling; Constraints; Low Level Heuristics.

---

### 1. Introduction

The solution for curricula scheduling requires the assignments of the suitable venue (class-room or Lab) and personnel (Teacher, Lab Assistant etc.) over proactively identified transected point (slot) which also includes the multiple number of time variables (day, session and period) for different offered courses to students group (Curricula). The classic or manmade model essentially requires exhausting efforts only to obtain workable solution, on the other hand, along with other AI based computational models the Hyper-heuristic is the state-of-the-art solving technique and fairly capable to produce optimum results against exceedingly complex datasets. The set of low level heuristics (LLH) is unarguably a significant part of any hyper-heuristic framework. Usually the low level heuristics are designed according to domain specification. This article illustrates a small number of heuristics which is brief part of ongoing research project. In the said project the Low Level heuristics are categorized into several groups according to their relevant scope, functionality and process of interaction as shown in Table 2. The random low level heuristics apply to scatter the event variables over the properly formulated layout; as a result the some targeted slots can be vacated among others. Alternatively, incremental or progressive LLHs gradually try for positive changes and improve the efficiency or maintain its preceding state. The set of heuristics are supposed to make some progressive moves in datasets. This article is expansion of research work published by [1] and shown the functionality of four more important low level heuristics (LLH<sub>8</sub>, LLH<sub>9</sub>, LLH<sub>10</sub>, LLH<sub>11</sub>).

### 2. Related work

‘Course (Curricula) timetable is integral part of academic calendar in order to commence the curriculum activities and later on regulate smoothly’ [2]. The problem solution essentially depends upon the maximum satisfaction of the

constraints (Hard and Soft Constraints). ‘Hard constraints [3] exceptionally should remain unbreakable under all circumstances. On the contrary all soft constraints cannot be satisfied in conventional problem instances although maximum satisfaction has decisive impact on solution feasibility’. Sometimes the two types of constraints are handled with distinctive solving approaches [2]. Designing data structures for dataset (description of events, resources and constraints) is significant step. ‘An efficiently designed scheduling layout not just makes dataset comprehensible apparently, but greatly helps to converge error-free order of events. Each event-slot is a cross point between period and location. In that consequence, there is no chance of resources replication constraint e.g. Single class room allocation for two course’[4]. Computed initialization of dataset can be the part of solving hard constraints. Ahmed [5] implemented backtracking recursive algorithm for obtaining twofold tasks including placement of the Events and elimination of the Hard constraints. In the research article [6] introduces a novel evaluation function that accurately scans out soft and hard violations in the dataset and consequently assigns penalties to conflicting events. Contemporary research direction in TTP is tending to raise the level of generality by state-of-art techniques so that a range of instances can be tackled. Hyper-heuristic is one of such modern-day techniques that largely shape such idea[7], [8].

### 3. Problem description

Curricula scheduling is a composite issue consists of several components such as Lecturer, Location, Course, Session, Duration and Students. So that formulation of Timetabling is TTS-Problem = [I, T, C, S, G]. The University Scheduling Problem hence is optimization of finite resources. Simply, the solution concludes the suitable location (Classroom) and resource personnel (Lecturer) on certain time-point (Day and Session) for the group of students (Curricula).

#### 3.1. The problem terminology

- *Event*: An academic activity (Lecture) independently organized on distinct time.
- *Time-Slot*: Juncture point among resources (Lecturer or allocated Classroom) and time-point to hold the event.
- *Session*: stack of time-slots for running of several events.
- *Working Day*: A working day is combination of several sessions.
- *Physical Resource*: Classrooms, Buildings, Lab equipment, Personnel etc.
- *Group*: Enrolled students for the course(s)
- *Curricula*: Set of related optional or compulsory programs (courses).

#### 3.2. Constraints penalty schemas

The penalty schemas are set of weights for constraints violation. The schema shares some global constraints and their penalties weight along with a few personalized constraints. These schemas belong to core performance measures. The sample penalty weights are reflected in Table 1, their raised level of complexity can be observed on each increasing scale. This penalty cost scheme is defined by Alex Bonutti et al [9]. In this work, one extra scale is added in all benchmark instances as shown in Table 1. Each Scale is started with a different list of penalty weights according to schemas. The evaluation function is multiple of the penalty cost with number of violation occurrences. The degree of complexity increases with the size of instance. The hard constraints (HCn) in Table 1 stand compulsory for feasibility level of solution. On the contrary, the satisfaction of soft constraints is significantly essential to obtains optimum results.

**Table 1:** Problem Classification Description[8].

Var.	Type	Constraint Label	Complexity Scales(1-6)					
H <sub>1</sub>	Hard Constraints	Lectures	H	H	H	H	H	H
H <sub>2</sub>		Conflicts	H	H	H	H	H	H
H <sub>3</sub>		Room Occupancy	H	H	H	H	H	H

## 4. Methodology

The set of low level heuristics (LLHs) is essentially a core component of hyper-heuristic (HH) structure. Generally, LLHs are designed specifically for domain specification. Each LLH operates a small shift in current state of solution.

**Table 2:** Group of Classified Low Level Heuristics[1].

ID	Algorithm Name	Scope	Function	Interaction
LLH <sub>1</sub>	Shift_MaxPenalizedDayToTail	Day	Shift	Semi -R
LLH <sub>2</sub>	Shift_MaxSaturatedDayToTail	Day	Shift	Semi -R
LLH <sub>3</sub>	Shift_LessSaturatedDay	Day	Shift	Semi -R
LLH <sub>4</sub>	Shift_DayConstToLessSituDay	Day	Shift	Semi -R
LLH <sub>5</sub>	Shift_WithDayConstImprov	Period	Shift	Progressive
LLH <sub>6</sub>	Swap_InDays	Period	Swap	Semi -R
LLH <sub>7</sub>	Shift_RandDayImprovement	Day	Shift	Progressive
LLH <sub>8</sub>	Swap_InColumn	Period	Swap	Progressive
LLH <sub>9</sub>	Shift_NeighboringPeroid	Period	Shift	Random
LLH <sub>10</sub>	Swap_InRows	Period	Swap	Progressive
LLH <sub>11</sub>	Shift_Dispersions_of_Exam	Day	Shift	Progressive

Table 2 exhibits the classification of Low Level Heuristics (LLHs) designed and developed in this research project, however last four LLHs are described in this article. The some LLHs are laying either in Shift or Swap functionality. The Shift based LLH moves the penalized data string to calculated vacant place whereas Swap function mutually interchange two events, this technique is useful in condensed problem instances. Random LLHs are used to throw the events faraway on the layout because the vacuities among the slots are required. Semi-Random category of LLHs picks the conflicting events out using predefined criteria and shift to diverse locations randomly. On the contrary, progressive LLHs in fact make positive move and improve or sustain the state. Figure 1 reflects the transaction of level of low level heuristics over problem instances.

**Fig. 1:** Hyper-Heuristics Framework [1].

### 4.1. LLH<sub>8</sub>: Swap in column

Figure 02 and LLH<sub>8</sub> algorithm illustrates a heuristic which is applicable in swapping of two events in scope of single session. The LLH is designed to address specifically some column level constraints for example the Room Constraint is very obvious target of this LLH. The LLH<sub>8</sub> is fundamentally a progressive operator, if it appears to be successful than outcome gets accepted otherwise the prior solution state becomes reinstated.

**Algorithm LLH<sub>8</sub>: Swap\_InColumn**

```

DEF Swap_InColumn(key1, 'Peroid'):
1. FOR k IN range (1, Rooms):
    a. IF Layout[k] IS None:
        key2 = k
    b. ELIF Layout[k]['Penlty'] != 0:
        key2 = k
    c. ELIF Layout[k]['PenType'] == 'P':
        key2 = (key1 [0], key1[1],k)
    d. ELSE: key2 = None
2. IF key1 AND key2:
    a. SwapSlots(key1,key2)
    b. ResetFitness(Day)
    
```

**Fig. 4:** Exchange of Slots In Row

#### 4.4. LLH<sub>11</sub>: Shift dispersions of exam

Heuristics LLH<sub>11</sub> is gray shaded heuristics which might be used for exam and curricula timetabling. The same heuristic is discussed in [10] with PSO-Hyper heuristic for solving examination scheduling however in this study the said heuristic is member of curriculum solving LLHs, here the set is supervised by Genetic-Hyper heuristic. The LLH<sub>11</sub> finds the difference between two timeslots, if there is no marginal gap than procedure moves the slot to less saturated day of the layout. The shifting process is inclined to increase in fitness function. Thus it operates on positive change if found in solution otherwise it calls the rollback action.

**Algorithm LLH<sub>11</sub>:** Shift\_Dispersions\_of\_Exam

---

```

DEF Shift_Dispersions_of_Exam
1. (t1,t2) = ScanWeek()
2. IF |ti - ti+1| ≤ 1
   Then
    a. Saturated_Day_key = MaxOfDay(t1,t2)
3. IF Less_Saturated_Day_key NOT none
   Then
    a. Less_Shift_DayToEnd(Saturated_Day_key)

```

## 5. Results

The partial experimental results of research prototype are showing the worth of research direction, this section briefly reflects them. The outcome is examined by a properly calculated performance measures. The project components are written and compiled over Lenovo® Intel CORE™ i3, 2.27 GHz, 4.00 GB RAM. The Python language version 2.7 and its supplement libraries are chosen to shape the project.

Table 3 exemplifies the two sample results of benchmark instances, which are grouped over six distinct complexity scales. Datasets are varying from each other on the basis of extended size of parameters including problem density (involvement of constraints categories), saturation (shortage of resources) and complexity level (increasing number of constraints). These results are generated by Hyper-Heuristic along with various other components as discussed in Related Work section and said heuristics LLH<sub>8-11</sub> were part of that compilation.

At the first the results reflects mutual and mandatory feature that the all the Hard Constraints are completely removed from layout and soft constraints are minimized to certain degree, however few of the soft violations remained unsolved in most of the cases.

## 6. Conclusions

In this research work, a subset of novel group of low level heuristics is elaborated. LLH(s) are addressing the multiple sets of benchmark datasets. All the LLHs are divided under three main categories. The outcomes revealed that each category have some targeted constraints where it can produce quality ‘move’ and it also demonstrate that solo category is not capable to produce sufficient level of outcomes however Hyper-heuristic managed various groups of LLHs promisingly produce optimal outcome.

## Acknowledgment

This is the extended version of article [11] published as conference proceedings of ICCET 2013 held on March 5-7, 2013. In addition, as this study reflects only the small part of ongoing research project so some of the tables, figures and results are inherited from previous publications of same project in order to convey the notion properly.
