Abstract

The study was investigated to enhance biogas production from rumen digesta by anaerobic co-digestion process. The experiment was carried out in 3300 mL digester. The mixing ratio of rumen digesta and water used was 1:1 in 40 days Hydraulic Retention Time (HRT). Produced gas was measured by volumetric water replacement method. In phase-1, the maximum biogas generation from digesta of chicken and goat, cow and chicken, cow and goat, and co-digestion of four substrates (C:CH:G:V) were 65, 1230, 37 and 375 mL/d at 17th, 14th, 26th and 13th day respectively. The average biogas production was found from these samples were 20, 340, 16 and 113 mL. In phase-2, the maximum biogas generation from cow, goat and chicken, cow, chicken and vegetable waste and cow, goat and vegetable waste were respectively 66, 80 and 64 ml/d at 19th, 23rd and 27th day. The average biogas generation were found from these samples 22, 32 and 19 mL. The comparative data shows, biogas production is higher with cow and chicken wastes in both the phases mixed with vegetable waste. Thus, it is suggested that the study which gave maximum yield of biogas production from co-digestion process might be met the future energy demand.

Keywords: Biogas; Co-Digestion Process; Fossil Fuel; Renewable and Non-Renewable Energy; Rumen Digesta.

1. Introduction

On the last decades, anaerobic digestion is used as a process to treat organic solid wastes became more and more frequent. The reason of this new tendency for the treatment of solid wastes can be explained considering mainly three factors [1-3]: i) the need to apply a process to the disposal of organic solid wastes more environmental friendly than landfills as requested by the latest rules concerning the environmental protection in many countries in the world; ii) the opportunity to obtain a renewable fuel called biogas from this process is an alternative to fossil ones; iii) the advantage of this process is relatively low costs in starting up and management.

The exhaustion of fossil fuels and the global warming situation are strong motivating factors for alternatives fuels research. Many countries are showing their interest in sustainable renewable energy sources such as; geothermal power, wind power, small-scale hydropower, solar energy, biomass energy, tidal power, and wave power [4]. Biomass energy is environmentally friendly and requires less production energy [5]. Various biomasses derived from the carbonaceous waste of human, animals and natural resources could be utilized as renewable energy resources [6]. Solutions to waste problems such as food waste and manure including gasification, pyrolysis and plasma technologies (incineration) of solid wastes have been developed [7]. These technologies involve the combustion of organic waste at elevated temperatures in the absence of oxygen. These technologies require a lot of energy to operate, and some facilities consume more energy than what they can produce [7]. Microorganisms transform biodegradable substrates into biogas and stabilized solid residues could be a better option [8]. Generally fossil fuels contain high percentages of carbon and include petroleum, coal, and natural gas. Fossil fuel ranges from volatile materials with low carbon to hydrogen ratios like methane, to liquids like petroleum, to nonvolatile materials composed of almost pure carbon, like anthracite coal. Methane can be found in hydrocarbon fields either alone, associated with oil, or in the form of methane clathrates. The use of fossil fuels is raising serious environmental concerns of carbon dioxide is produced per year. Carbon dioxide is a greenhouse gas which increases the radioactive forcing and contributes to the global warming. A global movement towards the generation of low-carbon renewable energy is underway to help reduce global greenhouse gas emissions.

Renewable energy sources are an effective and efficient solution to mitigate this alarming problem. Renewable energy source are those sources which are naturally replenished on human timescale such as wind, sun, rain, wave. To produce renewable energy, rumen digesta may be useful source. Rumen digesta is mainly animal waste. The reticular rumen is a large chamber in which ingested feed is first subjected to microbial digestion. Disposal system of rumen waste may create environmental pollution, result in health hazard to human due to the presence of millions of microorganisms and also causes water pollution by entering into rivers, streams and other local sources. It is also responsible for greenhouse effect because of conversion into methane and carbon dioxide. Methane gas is 23 times more potent greenhouse

gas than carbon dioxide. Pathogenic organisms are also found in slaughterhouse wastes including *Clostridium perfringens*, *vibrio* sp. The environmental pollutions can be prevented by recycling rumen digesta. One of the key methods to recycle rumen digesta is to produce biogas as a renewable energy source and can also produce bio-fertilizer and feeder by recycling rumen digesta.

Biogas can be defined as a mixture of different gases which are produced by the breakdown of organic matter in the absence of oxygen in closed system is called an anaerobic digester, biogas digester or a bioreactor. Biogas a gaseous mixture which is mainly composed of methane and carbon dioxide through the concerted action of a close-knit community of bacteria. The process of biogas production is divided into four steps [9]. Hydrolysis is a reaction with water. Acid and base are used to accelerate the reaction, and this is also occurring in enzymes. The cellulose, starch, and simple sugars can be broken down by water and enzymes. During acidogenesis, soluble monomers are converted into small organic compounds, such as short chain (volatile) acids (propionic, formic, lactic, butyric, succinic acids, ketones (glycerol, acetone), and alcohols (ethanol, methanol). The acidogenesis intermediates are attacked by acetogenic bacteria; the products from acetogenesis include acetic acid, CO₂, and H₂. The last phase of anaerobic digestion is the methanogenesis phase. Several reactions take place using the intermediate products of the other phases, with the main product being methane.

There are many studies available on biogas production from cow dung, solid waste. Al Mamun and Torii conducted an experiment to regulate the potential biogas production from different mixing ratios of vegetable, fruit & cafeteria waste [10, 11]. Rouf et al. conducted an experiment to know the potential of biogas production from slaughter house waste and to know the optimum condition for production [12]. Peyman Abdeshahian et al. studied on the potential of biogas production from farm animal waste [13]. But there are few remarkable studies on enhancement of bio-methane production from rumen digesta by co-digestion process. A study focused on waste reduction that comes from slaughter house and also investigated the possibility of biogas production from rumen waste. Salleh et al. found that Biogas production can be improved using dairy manure and rumen fluid [14]. Oporum et al. investigated on production of biogas from fish pond effluent supplemented with cow blood [15]. Manimuthu et al. conducted an experiment to know the effect of Agar waste on biogas production from the co-digestion of rumen waste [16]. Budiyo et al., demonstrated the ability of biogas production from slaughter house waste (rumen fluid, rumen digesta, cow dung) [17]. According to Ambar Pertiwiningrum et al. addition of rumen fluid reduces the time which is required for the initial phase of decomposition (hydrolysis and acidogenesis) compare with methane formation phase [18]. D.A. Putri et al. use cow manure coupled with rumen fluid and water for production of biogas. The study showed the influence of manure, rumen and water in biogas production [19]. Yasunori Baba et al. conducted an experiment with rumen fluid. According to experiment, pretreatment of waste paper with rumen fluid increase methane yield [20]. Sunarso et al. studied on the effect of rumen fluid of animal ruminant to increase biogas production from cattle manure at mesophilic condition [21]. This study focusses on enhancement of bio-methane production as a renewable energy source by co-digestion process of rumen waste with kitchen waste to control environmental pollution.

2. Materials and methods

2.1. Collection of raw material

Rumen waste of cow used for the experiment was collected from slaughterhouse of Shibganj and Mirabazar. Chicken waste was collected from the slaughter house of Eidgah and Baluchor bazaar. Rumen waste of goat was collected from slaughterhouse of Mirabazar. Vegetable waste was collected from the Baluchor bazaar. The collected raw material was stored at 4°C and used for experiment. Rumen digesta contain some undigested food such as grass, straw, grain.

2.2. Sample preparation

For the first phase, rumen waste of cow, chicken, goat was weighted and made four sample for fermentation. Four mix samples of two types of rumen waste was prepared and mixed in the ratio of waste of chicken: goat 1:1, cow: chicken 1:1, cow: goat 1:1. A mix sample of four types of rumen waste was prepared and mixed in the ratio of Cow:Chicken: Goat:Vegetable (C:CH:G:V) 1:1:1:1 were diluted with water and mixed properly to obtain homogenous condition. P^H of sample was measured of 6.6, 6.8, 6.6, and 6.9 for cow, chicken, goat and mixture of cow, chicken, goat rumen digesta with rumen fluid respectively.

Table 1: Amount of feedstock's used in the reactor

Reactor	Rumen waste (Kg)	Water (L)	Amount of material (Kg)
Phase 1			
R1 (Chicken + Goat)	0.68*2	1.36	2.72
R2 (Cow + Chicken)	0.68*2	1.36	2.72
R3 (Cow + Goat)	0.68*2	1.36	2.72
R4 (Cow + Chicken + Goat + Vegetable)	340*4	1.36	2.72
Phase 2			
R5 (Cow + Goat + Chicken)	0.45*3	1.36	2.72
R6 (Cow + Chicken + Vegetable)	0.45*3	1.36	2.72
R7 (Cow + Goat + Vegetable)	0.45*3	1.36	2.72

In second phase of the experiment, rumen waste of cow, chicken, goat was weighted and made three samples for fermentation. Three mix sample of three types of rumen waste was prepared and mixed in the ratio of waste of cow:goat:chicken 1:1:1, cow: chicken: vegetable 1:1:1, cow: goat: vegetable 1:1:1. P^H of sample was measured of 6.8 for cow, 6.2 for chicken, 6.8 for goat, 7.3 for vegetable. The size of beaker is 3300 mL. 80% of beaker (2.72 kg) was filled with material 1:1 which is 0.68 kg and 0.45 kg each for first and second phase. Kitchen substrates were blended the substrates for homogeneous mixture by making small particle size in 0.5 mm to 10 mm for both phases with the help of electric blending machine. The quantity of rumen digest used in reactors is shown in Table 1.

2.3. Experimental set up

The lab scale experimental set up was started by using four 3300 mL digester, water cum chamber and water collector for every observation. The temperature range was 25°C to 30°C during the study period. The digester related to water chamber with a 12 mm hose pipe. Pipe was used to permit produced gas to flow from digester to water chamber. Gas creates pressure in water chamber and forced same volume of water to flow to water collector through another 10 mm hose pipe. One end of the gas pipe was connected to the top of digester with a glass

tube and other part was connected to the top of the water chamber. One part of water pipe was connected to the top of the water chamber and other part of pipe was connected to the water collector. A gas control valve was attached with hose pipe to control the flow of produced gas. Other material used for that experiment include thermometer, pH meter, glass tube, gas pressure gauge, gas flow control valve, graduated plastic bucket, beaker, hosepipe. Biogas production was monitored during study period. The data of 40 days Hydraulic Retention Time (HRT) was recorded. The schematic diagram of experimental set up is shown in Fig. 1.

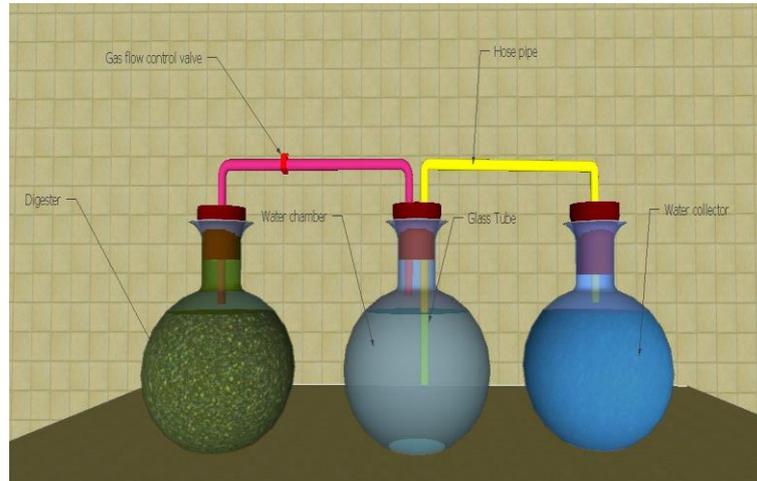

Fig. 1: Schematic Diagram of Experimental Set Up.

2.4. Data collection of produced gas

In this experiment the amount of produced gas was measured by water displacement method. Data was collected every day at 12 pm in the Agricultural and Biosystems Engineering Lab at Sylhet Agricultural University. Slurry was Pulverized inside biogas digester by hand shaking the reactor to stimulate bacterial activity and release the biogas avoiding sedimentation of the fed materials under the biogas reactor during the data collection of 40 days Hydraulic Retention Time.

2.5. Observation

In the first phase experiment (1), four observations were started after filling the digester with rumen waste of chicken and goat, cow and chicken, cow and goat, and mixed rumen waste. After filling, digester was left for anaerobic digestion and gas was started to produce from second operating day and it was almost finished at 39/40th digestion day. Produced gas was permitted to flow through pipe into water chamber and forced same volume of water to flow into water collector through hose pipe. Produced gas was measured directly through the measurement of the same volume of displaced water. Observation was continued till the flow of displaced water was stopped.

In the second phase experiment (2), three observations were started after filling the digester with rumen waste of cow, goat and chicken, cow, chicken and vegetable, and cow, goat and vegetable. After filling, digester was left for anaerobic digestion and gas was started to produce from first operating day and it was almost finished at 39/40th digestion day. Observation was continued till the flow of displaced water was stopped following the same procedure of first phase experiment.

2.6. Analytical method

The kitchen wastes were blended using Sahara pride mixer grinder (750W, RTG 30 MIN, 18000 RPM, VK Group of Industries, INDIA). The samples were taken and measure pH by pH tester (HI98107, HANNA Instruments, Inc. Romania). Thermometer (TP300, China) was used to keep record daily temperature of study period as well as daily ambient temperature of the environment. Temperature range of TP300 thermometer is -50°C ~ +300°C. Microsoft Excel 2013 software was used to make the graphical analysis.

3. Results and discussion

3.1. Biogas production profile

Fig. 2, represents the daily production of biogas from rumen digesta and kitchen waste in phase 1. Under 40 days Hydraulic Retention Time (HRT), the production starts from the first operating day due to the rapid decomposition of undigested feedstock of chicken and goat. Production was gradually increased from the 5th day to 17th day. Then production was decreased due to temperature fall and digestion of slurry. Maximum gas production was 65 mL/d which was recorded in 17th day of study period. The average rate of gas production was 20 mL/d.

The highest production rate of biogas from cow and chicken rumen waste was 1230 mL/d at 14th day with high fluctuations due to pH and temperature variation under 40 days Hydraulic Retention Time (HRT). The average gas production was 340 mL/d. This study shows that the production of biogas from cow and chicken digesta was more than chicken and goat digesta. Although production does not start from the beginning day and production rate was very low compared to zero because rumen digesta of cow which also contain some undigested food such as grass, straw, grain which decomposed slowly which was indicated the upward trend of the graph after first 6 days.

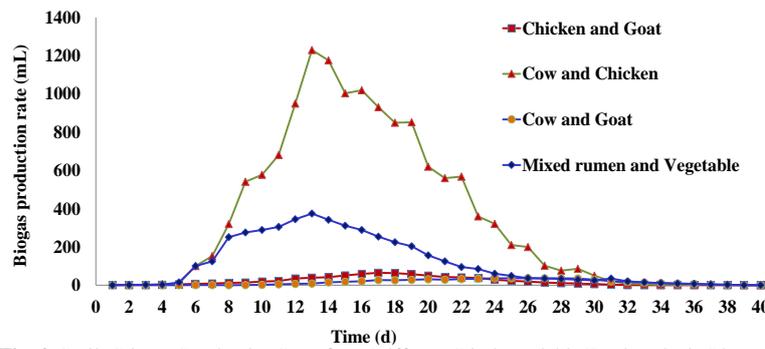

Fig. 2: Daily Biogas Production Rate from Different Biodegradable Feedstocks in Phase 1.

The results also showed that, the maximum production rate of biogas from cow and goat rumen waste was 37 mL/d at 26th day. After 29th day of digestion period production decreased and continued to decrease up to 40th day. The average rate of production was 16 mL/d. The undigested waste of cow needed more time to digest and undigested waste of goat needed less time to decompose as a result, at the beginning of retention period the biogas production rate was less.

Moreover, production of biogas from co-digestion of cow, chicken, goat and vegetables as shown in Fig. 2. Biogas production started from the 5th operating day. Production was high at the first few days. Maximum production was 375 mL/d obtained at the 13th day. Rate of production varied with temperature. The average rate of biogas production was 114 mL/d. The general prediction is that production rate directly related with the growth of methanogenic bacteria, temperature and p^H . The investigation was observed that the biogas production rate was almost stabled from the 31st day to 40th day. The study result reveals that biogas production rate was not highly fluctuated over the digestion period.

Fig. 3. represents that the production rate of biogas from cow, goat and chicken waste. The production does not start from the beginning day and production rate was very low compared to zero because rumen digesta of cow contains some undigested feedstock such as grass, straw, grain which decomposed slowly. Under 40 days Hydraulic Retention Time (HRT), the highest gas production was 66 mL/d at 19th day with high fluctuations due to temperature variation. The average gas production was 22 mL/d.

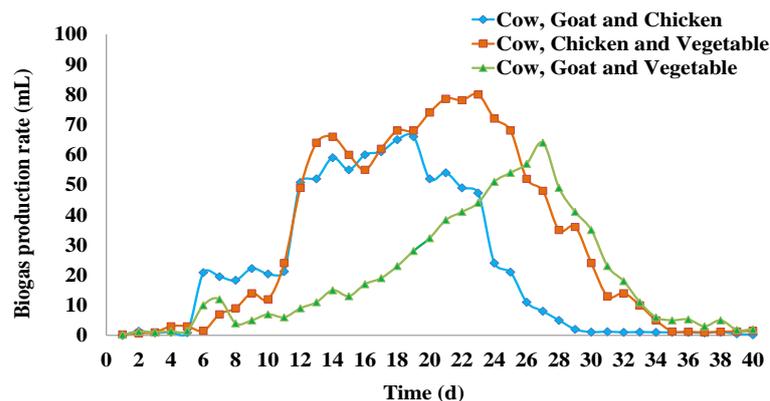

Fig. 3: Daily Biogas Production Rate from Different Biodegradable Feedstocks in Phase 2.

This experiment was found that the maximum production rate of biogas from rumen digesta of cow, chicken and vegetable waste was 80 mL/d at 23th day. After 23th day of digestion period production was sharply decreased and continued to decrease during the study period. The average rate of production was 32 mL/d. At the beginning of retention period the biogas production rate was less. The investigation was observed that the biogas production rate was almost stabled from the 35th day to 40th day.

The maximum production of gas was 64 mL/d was recorded in 27th day of study period from cow, goat and vegetable waste as shown in Fig. 3. At the beginning of retention period the biogas production rate was less. The biogas production rate was gradually increased from the 1st day to 7th day. The average rate of production was 19 mL/d. The investigation was observed that the biogas production rate was almost stabled from the 34th day to 40th day due to the fluctuations due to temperature variation.

3.2. Comparison profile of biogas generation

Fig. 4, represents the difference in biogas production after every 10 days in first phase. This figure reveals that after 10 days production was low in every digester except in digester which was filled with cow and chicken rumen waste. The figure also shows that biogas production from cow and chicken rumen waste were increased in 2nd 10 days and then decreased in 3rd and 4th 10 days because of the highly decomposed rate was occurred after 10 days. Production of gas from cow and goat rumen waste was decreased in 1st, 2nd and 4th 10 days compared with in 3rd 10 days. The figure shows that production of gas from mixed waste of cow, chicken, goat and vegetable were firstly high in 1st 10 days and gradually increased in 2nd 10 days because of co-digestion of three substrate ratio and vegetable waste i.e. protein, nitrogen increased production. When vegetable waste became digested fully production rate decreased in 3rd and 4th 10 days. Figure also shows that highest gas produced from chicken and goat, cow and chicken, cow and goat and mixed rumen waste was 484, 931, 4, 340, and 2806 mL/d in 2nd, 2nd, 3rd and 2nd 10 days respectively.

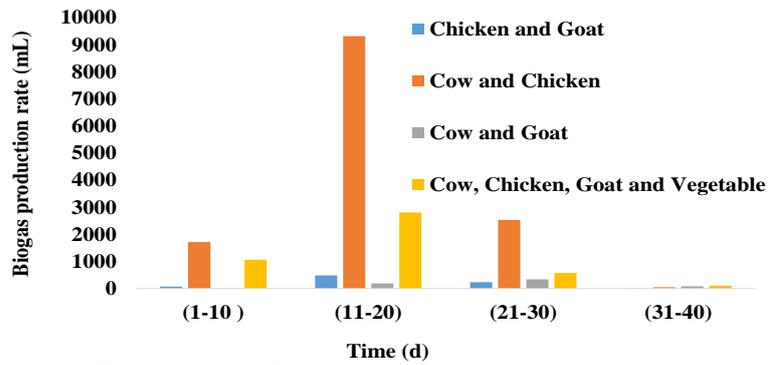

Fig. 4: Variation of Gas Production After Every 10 Days in Phase 1.

Fig. 5, represents the difference in biogas production after every 10 days in second phase. This figure reveals that after 10 days production was high in every digester except in digester which was filled with cow, goat and vegetable waste. The figure also shows that biogas production from cow, chicken and vegetable waste were increased in 2nd and 3rd 10 days then decreased in 4th 10 days because of the highly decomposed rate was occurred after 4th 10 days. Production of gas from cow, goat and vegetable waste were decreased in 1st, and 4th 10 days and increased in 2nd and 3rd 10 days. The Figure shows that production of gas from cow, goat and chicken were firstly less in 1st 10 days and gradually increased in 2nd 10 days because of co-digestion of three substrate ratio and vegetable waste gradually increased in 1st, 2nd and 3rd 10 days i.e. protein, nitrogen increased production and gradually decreased in 3rd and 4th 10 days for rumen digesta and 4th 10 days for kitchen waste means fluctuated over the retention time due to decomposed of feedstocks. The Figure also shows that highest gas produced from cow, goat and chicken, cow, chicken and vegetable and cow, goat and vegetable waste was 562, 590, 474 mL/d in 2nd, 2nd and 3rd 10 days respectively. The comparative data shows that biogas production is higher with cow, goat and vegetable wastes in both the phases mixed with the chicken waste.

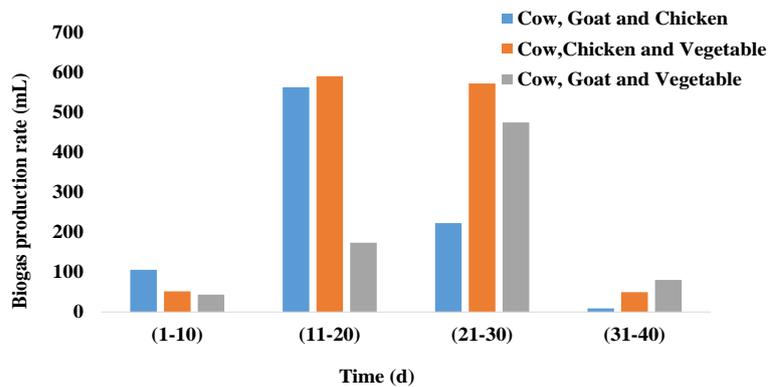

Fig. 5: Variation of Biogas Production After Every 10 Days in Phase 2.

3.3. Cumulative biogas production profile

Fig. 6, represent the cumulative biogas production from rumen waste of chicken and goat, cow and chicken, cow and goat and mixed waste. The figure shows that cumulative production of 812 mL (chicken and goat digesta), 13949 mL (cow and chicken digesta), 632.4 mL (cow and goat digesta) and 4662 mL (mixed waste) was observed in chicken and goat, cow and chicken, cow and goat and mixed waste respectively. Within 40 days of study period biogas production from rumen digesta was increased. The result shows that cumulatively highest production obtained at the last 10 days of study period. The average cumulative production of biogas from chicken and goat, cow and chicken, cow and goat and mixed waste were 480, 883, 3, 282, and 307, 9 mL/d respectively.

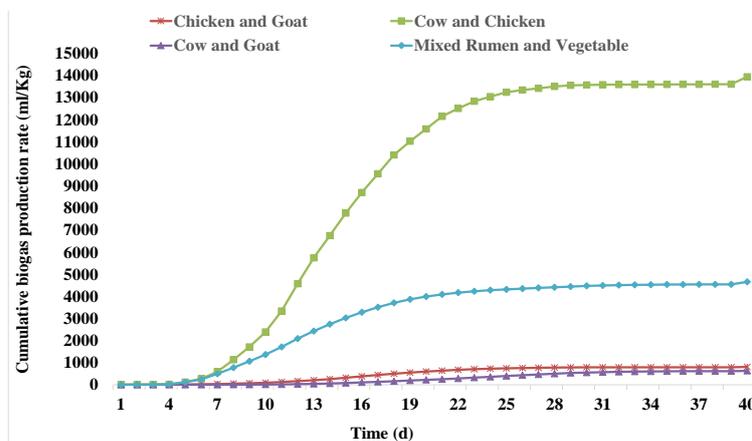

Fig. 6: Cumulative Biogas Production Rate in Phase 1.

Fig. 7, represent the cumulative biogas production from rumen waste of cow, goat and chicken, cow, chicken and vegetable waste and cow, goat and vegetable waste. The figure shows that cumulative production of 901 mL, 1294 mL and 772 mL was observed in cow, goat and

chicken, cow, chicken and vegetable and cow, goat and vegetable waste respectively. Within 40 days of study period biogas production from rumen digesta was increased. The result shows that cumulatively highest production obtained at the last 10 days of study period. The average cumulative production of biogas from chicken and goat, cow and chicken, cow and goat and mixed waste were 551, 689, and 341 mL/d respectively.

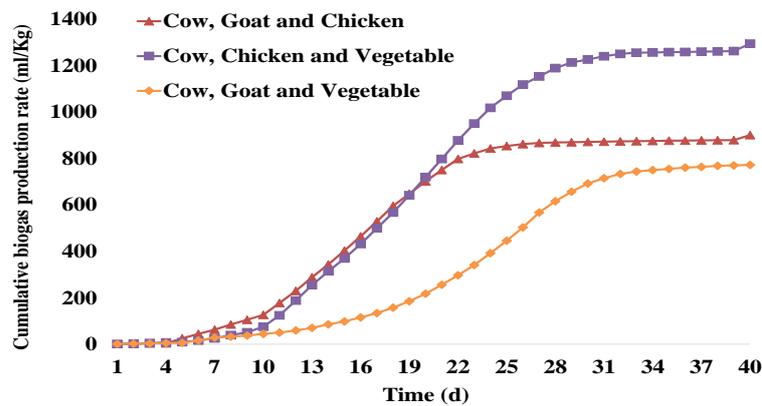

Fig. 7: Cumulative Biogas Production Rate in Phase 2.

3.4. Temperature profile

The daily temperature was noted during anaerobic digestion process. The temperature was in mesophilic range during study period. The lowest temperature was 23.5°C which was obtained on 3rd operating day in phase 1 and 22.6°C which was obtained on 32nd, 33th, 34th, 39th and 40th operating day in phase 2. The highest temperature was 32.4°C which was obtained on 29th operating day in phase 1 and was 27.3°C which was obtained on 1st operating day in phase 2. The average temperature was recorded 27.9°C in phase 1 and 24.3°C in phase 2 at the end of 40 days digestion time.

4. Conclusions

The scarcity of energy will be faced by the world in next few decades due to rapid growth of population. Renewable energy can be used as an alternative source to solve this problem. This study was to assess the enhancement of biogas yield from rumen digesta and kitchen wastes. The digestion of these substrates was conducted in two experiment under different seasons in batch type digestion system. In this study, rumen digesta were successfully digested and generated biogas. The first phase experiment was conducted in summer season and the average production of biogas from rumen digesta of chicken and goat, cow and chicken, cow and goat and cow, chicken, goat and vegetable waste were found 20, 340, 16 and 113 mL/d respectively. The second phase experiment was conducted in winter season and the average production of biogas from rumen digesta of (cow, goat and chicken), (cow, chicken and vegetable) and (cow, goat and vegetable) waste were found 22, 32 and 19 mL/d respectively. The data obtained from this study could be used as a basis for treatment of kitchen waste. The digestion of these substrates could be very promising way to provide renewable energy and remove environmental pollution.
